1.2. Determinazione valore vincolo elastico testa pali

Calcolo della rigidezza alla traslazione verticale dei pali in una palificata

Dati di ingresso:		
d	0,60	m
E_{palo}	31475806,21	kN/m²
V_s	485,00	m/s
ρ	1,94	kNs²/m⁴
G	455583,59	kN/m²
ν	0,30	
λ	69,09	

$\lambda = E_{palo} / G$

$A = (2 \cdot L / d) \cdot \tanh(\mu L)/\mu L$

$\mu L = (L / d) \cdot (2 / \lambda)^{0,5}$

$$k_1 = G \cdot \frac{d}{2} \cdot \frac{\frac{4}{(1-\nu)} + \pi \cdot \frac{A}{2}}{1 + \frac{4 \cdot A}{\pi \cdot \lambda \cdot (1-\nu)}}, \qquad k = \frac{k_1}{\sum_{j=1}^{N} \alpha_{i,j}}, \qquad \alpha_{i,j} = \frac{\ln\left(\frac{L}{s_{i,j}}\right)}{2 \ln\left(\frac{L}{d}\right)}$$

s_{ij} = distanza tra il palo i-esimo e il palo j-esimo

L = lunghezza del palo

d = diametro del palo

2. VERIFICHE IN TERMINI DI DEFORMAZIONE E VIBRAZIONE TRAVI IN C.A. ED ELEMENTI IN CARPENTERIA METALLICA

2.1. Verifiche in termini di deformazione travi in c.a.

Si riportano nella tabella seguente le frecce elastiche determinate mediante il modello di calcolo MODEST con riferimento alla combinazione SLE quasi permanente, ipotizzando la sezione interamente reagente rispetto alla configurazione deformata per le travi in c.a. che hanno luci elevate, oltre alle mensole della zona mezzanino.

Si precisa inoltre che le travi lunghe sono essenzialmente travi di chiusura laterale di campi di solaio alveolare, non direttamente caricate dagli stessi ma connesse mediante la cappa collaborante ai solai. Pertanto la deformazione delle travi è limitata dall'interconnessione con i solai, che essendo elementi in precompresso hanno frecce molto ridotte.

ID Trave	Luce [m]	Freccia f (mm)	Rapporto L/f
T202	11,64	3,88	3000
T204	11,64	1,45	8028

T716	11,64	1,53	7608
T717	11,64	4,36	2670
T326	3,50	2,79	1250
T330	3,50	1,94	1804

ID Trave	Luce [m]	Freccia f (mm)	Rapporto 2L/f (mensole)
T726	3,50	15,12	462
T730	3,50	7,07	990

Dalla tabella si osserva che il rapporto tra luce e freccia per le travi di interpiano è sempre molto elevato, ampiamente superiore ad 1/500 della luce. Per le travi di copertura che non portano tamponamenti il rapporto tra luce e freccia è sempre superiore a 1/250 della luce.

Per quanto riguarda l'abbassamento delle travi sotto il tamponamento vetrato del mezzanino (travi T326-T330-T-317) da modello strutturale si osserva un abbassamento in punta per le travi T326 e T330 dell'ordine di massimo 3 mm (in mezzeria non si hanno differenze significative in termini di inflessione per tali travi); per la trave 317 si ha un'inflessione in mezzeria di circa 8 mm. Le deformazioni, che risultano sempre superiori ad 1/1000 della luce, appaiono compatibili con la funzionalità della facciata vetrata soprastante, che comunque sarà realizzata a tratti di vetri contigui con struttura di supporto autonoma, in grado quindi di assorbire le deformazioni anche differenziali lungo lo sviluppo della facciata previste. Inoltre le facciate verranno posate quando gran parte della deformata si sarà già sviluppata per l'applicazione dei carichi statici strutturali e dei pacchetti di finitura.

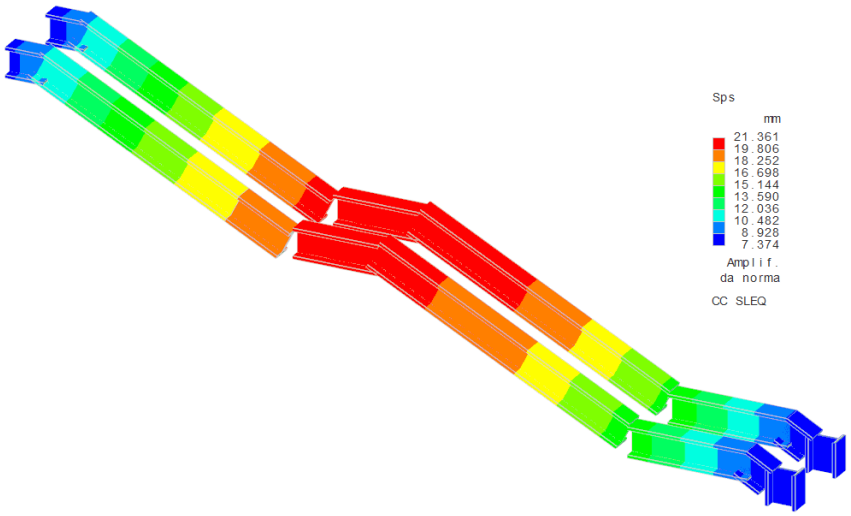
2.2. *Verifiche in termini di deformazione travi in carpenteria metallica*

Le verifiche in termini di spostamenti verticali delle travi in carpenteria metallica sono riportate negli output del modello di calcolo. Ad esempio per la trave HEB400 di bordo del solaio alveolare del mezzanino, precisando che la trave indicata è una trave di chiusura laterale di un campo di solaio alveolare, non direttamente caricata dallo stesso ma connessa allo stesso mediante il getto di calcestruzzo di completamento del solaio, si ha quanto segue:

```
- Verifica freccia massima per soli carichi accidentali - CC 40
fZ,G=0.45 (L/2669)

- Verifica freccia massima carichi totali - CC 40
fZ,L=1.42 (L/845)
```

Per gli scialoni delle scale in carpenteria metallica si riporta in figura seguente la deformata in combinazione SLE quasi permanente:



La freccia massima risulta di 21,36mm; considerando una lunghezza dello scialone complessiva di 12,57 metri da appoggio ad appoggio, si ha che la freccia massima è pari ad 1/588 della luce, superiore ad 1/500. Considerando l'asse della trave la lunghezza è di 13 metri, con una freccia pari a 1/608 della luce, superiore ad 1/500.

2.3. Verifiche in termini di vibrazioni travi in c.a.

Per effettuare le verifiche si è proceduto a determinare la frequenza fondamentale del sistema strutturale oggetto di verifica secondo la seguente formulazione:

$$f_0 = k \cdot \sqrt{\left(\frac{(E \cdot J)}{(M_d \cdot L^4)}\right)} \qquad f_0 \geqslant f_{min}$$

Con:

f0 =	frequenza fondamentale del sistema strutturale [Hz]
E =	modulo di elasticità [MPa]
J =	momento di inerzia [mm4]
Md =	massa derivante dalla combinazione frequente [t/mm]
L =	luce dell'elemento strutturale
k =	π/2 = 1,57 per elementi appoggio-appoggio, 3,56 per elementi incastrati agli estremi

La frequenza limite inferiore indicata dalla letteratura tecnica risulta di 3Hz (0,333 secondi) per solai ad uso residenziale e 5Hz (0,2 secondi) per solai di palestre, supporto impianti/macchine, scale. A favore di sicurezza le verifiche sono state effettuate con riferimento ad una frequenza limite di 8Hz (0,125 secondi).

Si riportano di seguito le verifiche effettuate per le travi di maggiore lunghezza e per le travi del mezzanino (T202 – T204 – T208 – T209 – T317 – T316 – T502 – T508 – T545 – T702 – T708 – T712 – T716 – T717 – T326 – T330). Il momento di inerzia è stato considerato nell'ipotesi di sezione parzializzata sulla base dell'armatura minima presente nell'elemento. Lo schema statico è sempre stato considerato cautelativamente di trave in semplice appoggio, minimizzando quindi la frequenza; per le travi di bordo dello sbalzo del mezzanino (T326-T330) si è considerato a favore di sicurezza lo schema di trave in semplice appoggio con luce doppia.

2.4. Verifiche in termini di vibrazioni travi in carpenteria metallica

Per effettuare le verifiche si è proceduto a determinare la frequenza fondamentale del sistema strutturale oggetto di verifica secondo la seguente formulazione:

$$f_0 = k \cdot \sqrt{\left(\frac{(E \cdot J)}{(M_d \cdot L^4)}\right)} \qquad f_0 \geqslant f_{min}$$

Con:

f0 =	frequenza fondamentale del sistema strutturale [Hz]
E =	modulo di elasticità [MPa]
J =	momento di inerzia [mm4]
Md =	massa derivante dalla combinazione frequente [t/mm]
L =	luce dell'elemento strutturale
k =	π/2 = 1,57 per elementi appoggio-appoggio, 3,56 per elementi incastrati agli estremi

La frequenza limite inferiore indicata dalla letteratura tecnica risulta di 3Hz (0,333 secondi) per solai ad uso residenziale e 5Hz (0,2 secondi) per solai di palestre, supporto impianti/macchine, scale. A favore di sicurezza le verifiche sono state effettuate con riferimento ad una frequenza limite di 8Hz (0,125 secondi).

Si riportano di seguito le verifiche effettuate per la trave HEB400 di bordo mezzanino e per gli scialoni HEB450 della scala in carpenteria metallica.

4.1. Tabelle di dimensionamento solaio di interpiano e solaio mezzanino

La luce del solaio è pari a 11,64 metri. La somma dei carichi G2 e Qes nel caso peggiore risulta pari a 600 daN/m2. In figura seguente si riporta il punto di lavoro che evidenzia come sia possibile realizzare il solaio previsto.

Il rapporto tra luce e spessore calcolato ai sensi della CNR 10025 risulta pari a 1164/(36+2,5) = 30,23 inferiore al limite di 35.

7. VERIFICHE SOLETTA IN LAMIERA GRECATA

Per la verifica della soletta in lamiera grecata si è effettuato un calcolo relativo alla sola sezione in calcestruzzo con armatura integrativa all'intradosso trascurando, a favore di sicurezza, il contributo della lamiera.

I carichi di progetto sono i seguenti:

G1 = 3,35 kN/m2 G2 = 1,80 kN/m2 Qes = 3,00 kN/m2

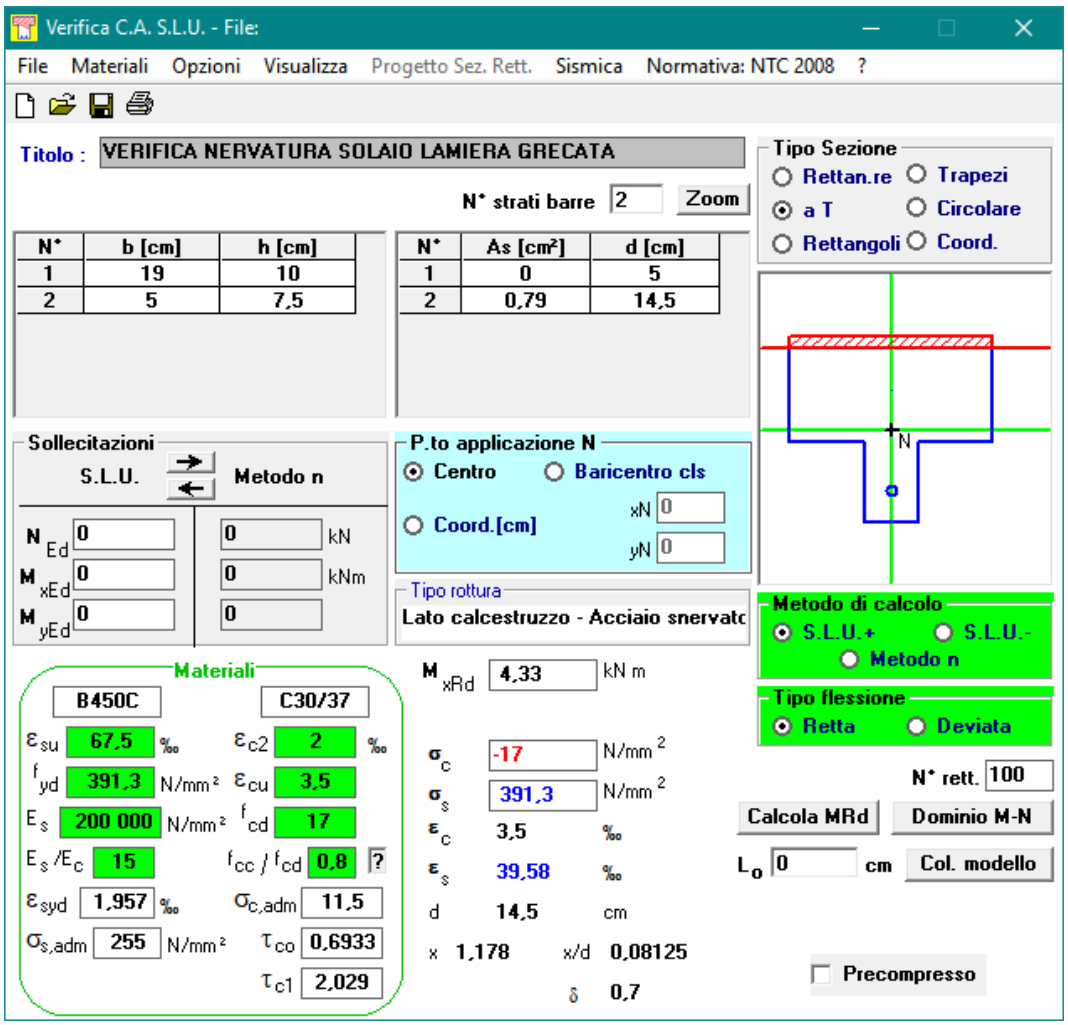
Il carico SLU a m2 risulta quindi pari a:

q,SLU = 1,3xG1+1,5xG2+1,5xQes = 11,56 kN/m2

Il passo delle nervature (lamiera EGB1200) è pari a 190mm (0,19m). Il momento SLU in campata sollecitante la singola nervatura viene calcolato, a favore di sicurezza, secondo lo schema di trave in semplice appoggio con 3,70 m di luce. Si ha:

MEd = q,SLU x 0,19 x $3{,}7^2/8$ = 3,76 kNm

Il calcolo del momento resistente effettuato con il software VcaSLU del Prof. Gelfi è riportato di seguito:



Il momento resistente di 4,33 kNm è superiore al momento sollecitante.
